Abstract

We present a fully abstract, denotational model for mobile, timed, nondeterministic data-flow networks whose components communicate in a point-to-point fashion. In this model components and networks of components are represented by sets of stream processing functions. Each stream processing function is required to be strongly pulse-driven and privacy preserving. A function is strongly pulse-driven if it is contractive with respect to the metric on streams. This property guarantees the existence of unique fix-points. The privacy preservation property can be thought of as an invariant specific to mobile point-to-point systems. Firstly, it guarantees that a function never accesses, depends on or forwards a port whose name it does not already know. Secondly, it guarantees that at the same point in time no port is known to more than two components, namely the sender and the receiver. Our model allows the description of a wide variety of networks — in particular, the description of unbounded nondeterministic networks. We demonstrate some features of our model by specifying a communication central.

1 Introduction

One of the most prominent theories for interactive computation is the theory of data-flow networks. In this theory, an interactive system is represented by a network of autonomous components which communicate solely by asynchronous transmission of messages via directed channels.

A very elegant model for static, deterministic data-flow networks, whose components communicate in a point-to-point fashion, was given by Kahn in [Kah74]. Despite of its elegant foundation, this class of networks is, however, too restrictive for many practical applications. In this paper we extend Kahn’s model in a number of ways.

Firstly, contrary to Kahn, we model nondeterministic behavior. Like Park [Par83], Broy [Bro87] and Russell [Rus90], we represent nondeterministic data-flow networks by sets
of stream processing functions. However, in contrast with [Par83] and Broy [Bro87], our model is fully abstract. This is achieved, by considering only sets of functions which are closed with respect to the external observations. The closure idea was used by Russell for the same purpose. However, contrary to Russell, we use a timed model and a different notion of observation. This allows us to describe a considerably greater class of networks. In particular, we can describe unbounded nondeterministic networks. Moreover, since our model is fully abstract, we obviously avoid the expressiveness problem known as the Brock/Ackermann anomaly [BA81].

Secondly, contrary to Kahn, we describe dynamically reconfigurable or mobile networks — networks in which every component may change its communication partners on the basis of computation and interaction. The formal modeling of mobility has been a very popular research direction in recent years. However, most models published so far have been formalized mainly in operational terms. Examples of such models are the Actor Model [HBS73, AMST92], the $\pi$–Calculus [EN86, MPW92a, MPW92b], the Chemical Abstract Machine [BB90], the Rewriting Logic [Mes91] and the Higher Order CCS [Tho89]. On the contrary, our model gives a denotational formalization of mobility. As in the above models, this formalization is based on two assumptions. Firstly, ports are allowed to be passed between network components. Secondly, the components preserve privacy: their behaviors do not depend on ports they do not know. Although it is well understood how to express privacy operationally, there is less denotational understanding. Informally speaking, our solution is to require each stream processing function to never receive on, send via or forward a port whose name “it does not already know”. By “the ports it does not already know” we basically mean any port which is not in its initial interface, it has not already received and it has not already created itself. Any port created by the function itself is assigned a “new” name taken from a set “private” to the component in question. This can be thought of as a privacy invariant satisfied by any mobile system.

In a companion paper [GS95a] we have shown how many-to-many communication can be modeled in this setting. In this paper we concentrate on point-to-point communication. There are basically two different variants of point-to-point communication. In the first case, the sender and the receiver of a channel remain the same during the whole lifetime of the channel. In the second case, the sender and the receiver of a channel may change. However, at any point in time a channel has not more than one sender and one receiver. In the first case there is no interference at all — two different components cannot send along the same channel. In the second case only a restricted type of interference may occur — two different components may send on the same channel, but never simultaneously. The advantage of the first alternative is its simplicity with respect to formal reasoning and understanding. The advantage of the second alternative is that many things can be expressed more directly. In this paper we concentrate on the second alternative. The first alternative is investigated in [GS95b].

Point-to-point communication is guaranteed by imposing local constraints on the way
ports are communicated. Some readers may wonder why we at all find point-to-point communication interesting. After all, point-to-point communication is only a special case of many-to-many communication. The main reason is that point-to-point communication allows a tight control of channel interference. In a point-to-point model the default situation is no interference at all (in the same time unit). Interference is only introduced via explicit fair merge components for those channels where this is desirable. In a many-to-many model there is interference by default. The tight control of interference in a point-to-point setting simplifies both specification (programming) and formal reasoning. Thus, our interest in point-to-point communication is methodological: we want to combine the power of nondeterminism and mobility with the simplicity of point-to-point reasoning.

Although we could have formulated our semantics in a cpo context, we decided to base it on the topological tradition of metric spaces [Niv82, dBZ82, AdBKR89]. Firstly, we wanted to understand the exact relationship between our approach and those based on metric spaces. Secondly, the use of metric spaces seems more natural since our approach is based on infinite streams, and since our pulse-drivenness constraint, guaranteeing the existence of a unique fix-point, corresponds straightforwardly to contractivity.

2 Basic Notions

We model an interactive system by a network of autonomous components which communicate via directed channels in a time-synchronous and message-asynchronous way. Time-synchrony is achieved by using a global clock splitting the time axis into discrete, equidistant time units. Message-asynchrony is achieved by allowing arbitrary, but finitely many messages to be sent along a channel in each time unit.

2.1 Communication Histories

We model the communication histories of directed channels by infinite streams of finite streams of messages. Each finite stream represents the communication history within a time unit. The first finite stream contains the messages received within the first time unit, the second the messages received within the second time unit, and so on. Since time never halts, any complete communication history is infinite.

Let $M$ be the set of all messages. Then $[M^*]$ is the set of all complete communication histories and $(M^*)^*$ is the set of all partial communication histories$^1$.

In the introduction we anticipated that components are allowed to communicate 	extit{ports}. A port is a 	extit{channel name} together with an 	extit{access right}, which is either a read right,

$^1$For an arbitrary set $S$, by $S^*$ we denote the set of finite streams over $S$, by $[S]$ we denote the set of infinite streams over $S$, and by $S^* \cup [S]$ we denote $S^* \cup \{[S]\}$. See also the appendix.
represented by ?, or a write right, represented by !. Let $N$ be the set of all channel names, then $?N = \{?n \mid n \in N\}$ is the corresponding set of read ports and $!N = \{!n \mid n \in N\}$ is the corresponding set of write ports. We also write $?! N$ for $?N \cup !N$. We assume that $?! N \subseteq M$. Let $D$ be the set of all messages not contained in the set of ports, i.e. $D = M \setminus ?! N$.

Since ports are exchanged dynamically between network components, each component can potentially access any channel in $N$. For that reason we model the complete input and output histories of a component by named stream tuples contained in $N \rightarrow [M^*]$. The partial ones are modeled by $N \rightarrow (M^*)^*$. In the sequel we will refer to named stream tuples of these signatures as named communication histories. Thus each named communication history assigns a communication history to each channel name in $N$.

### 2.2 Pulse-Driven Functions

A **deterministic component** is modeled by a stream processing function

$$f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*])$$

mapping complete named communication histories for its input channels to complete named communication histories for its output channels.

In accordance with the operational intuition, the functions process their input **incrementally** — at any point in the time, their output is not allowed to depend on future input. Functions satisfying this constraint are called **weakly pulse-driven**. If the output they produce in time unit $t$, is not only independent of future input, i.e. the input received at time $t + 1$ or later, but also of the input received during time unit $t$, then they are called **strongly pulse-driven**.

**Definition 1 (Pulse-driven functions)** A function $f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*])$ is weakly pulse-driven if

$$\forall \theta, \varphi, j : \theta \downarrow_j = \varphi \downarrow_j \Rightarrow f(\theta) \downarrow_j = f(\varphi) \downarrow_j,$$

and strongly pulse-driven if

$$\forall \theta, \varphi, j : \theta \downarrow_j = \varphi \downarrow_j \Rightarrow f(\theta) \downarrow_{j+1} = f(\varphi) \downarrow_{j+1},$$

where $\theta \downarrow_j$ represent the prefix of $\theta$ of length $j$.

We use the arrow $\rightarrow$ for the set of strongly pulse-driven functions.

**Theorem 1** A stream processing function is strongly pulse-driven iff it is contractive with respect to the metric of streams. A stream processing function is weakly pulse-driven iff it is non-expansive with respect to the metric of streams.

**Proof sketch:** Straightforward. The metric of named stream-tuples is defined in the appendix. \qed
2.3 Sum

The sum operator takes two named communication histories as input and delivers their “union” as output. We define both a partial “disjoint” sum and a total sum.

Definition 2 (Partial sum) Given two named stream tuples \( \varphi, \psi \in (N \rightarrow [M^*]) \) such that

\[
\forall i, n : \ \varphi(i)(n) = \epsilon \lor \psi(i)(n) = \epsilon.
\]

We define their partial sum \( \varphi + \psi \) to denote the element of \( N \rightarrow [M^*] \) such that for all \( i \in N, n \in \mathbb{N} \):

\[
(\varphi + \psi)(i)(n) = \begin{cases} 
    \varphi(i)(n) & \text{if } \varphi(i)(n) \neq \epsilon \\
    \psi(i)(n) & \text{if } \varphi(i)(n) = \epsilon
\end{cases}
\]

\( \square \)

Note that the partial sum has no syntactic conditions assuring its well-definedness. We therefore define a total version \( \varphi \oplus \psi \). This simplifies the use of the Banach’s fixed point theorem. Totalisation is achieved by defining \( (\varphi \oplus \psi)(i)(n) \) to be \( \epsilon \) if both \( \varphi(i)(n) \) and \( \psi(i)(n) \) are different from \( \epsilon \).

Definition 3 (Total sum) Given two named stream tuples \( \varphi, \psi \in (N \rightarrow [M^*]) \). We define the total sum \( \varphi \oplus \psi \) to denote the element of \( N \rightarrow [M^*] \) such that for all \( i \in N, n \in \mathbb{N} \):

\[
(\varphi \oplus \psi)(i)(n) = \begin{cases} 
    \psi(i)(n) & \text{if } \varphi(i)(n) = \epsilon \\
    \varphi(i)(n) & \text{if } \varphi(i)(n) \neq \epsilon \land \psi(i)(n) = \epsilon \\
    \epsilon & \text{if } \varphi(i)(n) \neq \epsilon \land \psi(i)(n) \neq \epsilon
\end{cases}
\]

\( \square \)

Note that \( \varphi \oplus \psi \) has a hiding effect if there are \( i \) and \( n \) such that \( \varphi(i)(n) \neq \epsilon \land \psi(i)(n) \neq \epsilon \), and that \( \varphi \oplus \psi \) is equal to \( \varphi + \psi \), otherwise.

Theorem 2 The total sum operation is weakly pulse-driven.

Proof: The sum \( (\varphi \oplus \psi)(i)(n) \) depends only on \( \varphi(i)(n) \) and \( \psi(i)(n) \).

\( \square \)

3 Privacy Preservation

A stream processing function \( f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*]) \) used to model a component is not only required to be strongly pulse-driven, but also to be privacy preserving. Firstly, privacy preservation guarantees that it accesses, depends on and forwards only ports it already knows. Thus, privacy preservation characterizes the way a function gains access to a port. Secondly, privacy preservation makes sure that a port is forgotten as soon as it is sent. This ensures the point-to-point invariant, namely that at any point in time the same port is known to exactly one function. Thus, privacy preservation also characterizes the way port access is lost.
3.1 Gaining Port Access

The way port access is gained can be described with respect to Figure 1, as follows. Initially, each stream processing function reads from a designated set of input channels $I$ and writes on a designated set of output channels $O$. These two sets name the static channels or the initial wiring. We require that $I \cap O = \emptyset$. To make sure that channels created by the different components in a network have different names, each stream processing function is assigned a set of private names $P$. Obviously, this set should be disjoint from the static interface. Thus we require that $(I \cup O) \cap P = \emptyset$.

During the computation, the sets of accessible channels can grow. For example, if the function receives a read port $?i$ then it may read from the channel $i$, and if it receives a write port $!o$ then it may write on the channel $o$. Similarly, whenever the function sends an output port $!j$, whose channel $j \in P$ it has created itself, it may later read what is sent along $j$, or whenever it sends an input port $?p$, whose channel $p \in P$ it has created itself, it may itself send messages along $p$ which eventually are read by the component which receives the input port.

![Figure 1](image.png)

At any given point in time $n$ and named input history $\theta$, by $\mathbf{ep}_{I,O,P}(\theta, f(\theta))(n)$ we denote the set of accessible external ports of $f$ and by $\mathbf{pp}_{I,O,P}(\theta, f(\theta))(n)$ we denote the set of private ports of $f$. When ambiguities do not occur we often refer to these sets as $\mathbf{ep}$ and $\mathbf{pp}$, respectively. For any set of ports $S$, $S_I$ and $S_O$ denote the subsets of input and output ports, respectively.

3.2 Loosing Port Access

To communicate in a point-to-point fashion a network of stream processing functions has to maintain the following invariant: at any given point in time, each port is “known” to at most one function. This means that for any channel $c$, at any point in time only two functions may access $c$, namely the sender and the receiver.

This point-to-point invariant is ensured by imposing local requirements on the behavior of functions.

Suppose $f$ sends one of its external ports $p \in \mathbf{ep}$ to some other function $g$ (see Figure 2). If $p = !o$ then both $f$ and $g$ have send access to $o$. Thus, $f$ may interfere with $g$ which is not what we want. Interference can also be the result if $p = ?i$ because in that case
both \( f \) and \( g \) may at some point in the future receive the same write port \(!o\) on \( i \). To avoid this risk of interference without losing compositionality we have to restrict any function to "forget" any port it sends along its output channels. Thus, with respect to our example, as soon as \( f \) forwards \( p \), it can no longer take advantage of this port, i.e., \( p \) is deleted from \( \text{ep} \).

Note that a function may send the same port several times because it may gain access to the same port several times. However, it may not send it more than once for each time it gains access to it. For example, if a function \( f \) initially has access to a port \( p \) and \( f \) forwards this port, then \( f \) must postpone sending it again until it has regained access to \( p \) by receiving \( p \) on one of its input ports.

Private ports may become public and public ports may become private. A function \( f \) may make a port \( p \in \text{pp} \) public by sending it to some other function \( g \). In that case both \( p \) and \( p^2 \) are deleted from \( \text{pp} \), \( \bar{p} \) is included in \( \text{ep} \) and \( p \) is "forgotten".

A public port becomes private if some function \( f \) receives some port \( p \) whose complement \( \bar{p} \) it already has in its set of public ports. After all, if \( f \) has both ports to a channel, then only \( f \) knows about this channel. Consequently, both \( p \) and \( \bar{p} \) should be added to its set of private ports \( \text{pp} \) and \( \bar{p} \) should be deleted from its set of public ports \( \text{ep} \).

We have described how functions gain access to and forget ports, and also how public ports may become private and the other way around. These are all local constraints. Since the function runs in an open environment these constraints are of course not sufficient unless the environment also plays the point-to-point game. After all, our local constraints are of no help if the environment behaves arbitrary. One way to deal with this problem is to impose an environment assumption and only require privacy preservation when this assumption is fulfilled. However, since we are only interested in environments which stick to the rules, we constrain our functions to ignore the input messages which do not respect the privacy restrictions.

We now explain how these constraints are imposed formally. First of all, since a function can only send the same port once for each time it gains access to a port, we only have to consider named communication histories in which the same port does not occur twice in the same time unit. A named communication history \( \theta \in N \to [M^*] \) in which the same port does not occur twice in the same time unit, i.e.,

\(^2\)Given a set of ports \( S \subseteq !N \). Then \( \overline{S} = N \setminus S \) and \( \overline{S} = \{ \bar{p} \mid p \in S \} \) where \( \bar{i} = !i \) and \( ?i = !i \). We also regard \( \theta(i)(n) \), when conveniently, as a set.
\forall n, p, i, j : p \in \theta(i)(n) \land p \in \theta(j)(n) \Rightarrow i = j

is said to be \textit{port-unique}. We use the arrow $\Rightarrow$ to distinguish named communication histories satisfying this port uniqueness constraint.

Port-unicity is preserved by the total sum if the two arguments never have an occurrence of the same port within the same time unit. More precisely, let the operator \texttt{prt} collect the ports occurring in a named communication history for each time $n$

\[
\text{prt}(\theta)(n) = \{ p \in ?!N \mid \exists i : p \in \theta(i)(n) \}.
\]

Then for $\varphi, \psi \in N \Rightarrow [M^*]$ such that for all $n$, $\text{prt}(\theta)(n) \cap \text{prt}(\phi)(n) = \emptyset$, it is the case that $\varphi \equiv \psi \in N \Rightarrow [M^*]$.

**Definition 4 (External and private ports)** Given $I, O, P, \theta$ and $\delta$. We define

\[
\text{ep}_{I, O, P}(\theta, \delta)(n) = \text{ep}_n, \quad \text{pp}_{I, O, P}(\theta, \delta)(n) = \text{pp}_n
\]

where $\text{ep}_n$ and $\text{pp}_n$ are given below.

\[
\begin{align*}
\text{ep}_1 &= \{ I \cup \neg I, \} \\
\text{ep}_{n+1} &= (\text{ep}_n \cup r_n \cup g_n) \setminus (s_n \cup h_n), \\
\text{pp}_1 &= \{ \neg P, \} \\
\text{pp}_{n+1} &= (\text{pp}_n \cup h_n) \setminus (s_n \cup \neg s_n),
\end{align*}
\]

where

\[
\begin{align*}
r_n &= \bigcup_{i \in \text{ep}_n} \{ p \mid p \in \text{pp}_n \cup \text{ep}_n \cap \theta(i)(n) \}, \\
h_n &= \{ p, \neg p \mid p \in r_n \land \neg p \in \text{ep}_n \}, \\
s_n &= \bigcup_{i \in \text{ep}_n} \{ p \mid p \in (\text{pp}_n \cup \text{ep}_n) \cap \delta(i)(n) \}, \\
g_n &= \{ \neg p \mid p \in s_n \land p \in \text{pp}_n \}
\end{align*}
\]

The sets $r_n, s_n, g_n$ and $h_n$ are the sets of received, sent, generated and to-be-hidden ports.

Let $\text{dom}_{I, O, P}(\theta, f(\theta))$ be the named input communication history actually read by $f$ and $\text{rng}_{I, O, P}(\theta, f(\theta))$ be the named output communication history which should be produced by $f$. The restricting functions $\text{dom}$ and $\text{rng}$ which are imposed to $\theta$ and $f(\theta)$ are defined below.

**Definition 5 (Domain and range)** Given $I, O, P, \theta$ and $\delta$. Let $\text{ep}_n = \text{ep}_{I, O, P}(\theta, \delta)(n)$ and $\text{pp}_n = \text{ep}_{I, O, P}(\theta, \delta)(n)$.

Then

\[
\begin{align*}
\text{dom}_{I, O, P}(\theta, \delta)(i)(n) &= \begin{cases} \\
\{ \text{ep}_n \cup \text{pp}_n \cup D \} \cap \theta(i)(n) & \text{if } i \in \text{ep}_n \\
\epsilon & \text{otherwise}
\end{cases} \\
\text{rng}_{I, O, P}(\theta, \delta)(i)(n) &= \begin{cases} \\
\{ \text{pp}_n \cup \text{ep}_n \cup D \} \cap \delta(i)(n) & \text{if } !i \in \text{ep}_n \\
\epsilon & \text{otherwise}
\end{cases}
\end{align*}
\]

**Theorem 3** The functions $\text{dom}$ and $\text{rng}$ are weakly pulse-driven.

**Proof sketch:** $\text{dom}_{I, O, P}(\theta, \delta)(n), \text{rng}_{I, O, P}(\theta, \delta)(n)$ depend only on $\theta|_n$ and $\delta|_n$.

8
Theorem 4 The functions $\text{dom}$ and $\text{rng}$ have the following properties:

\[
\begin{align*}
\text{dom}_{I,O,P}(\theta, \delta) &= \text{dom}_{I,O,P}(\text{dom}_{I,O,P}(\theta, \delta), \delta) = \text{dom}_{I,O,P}(\theta, \text{rng}_{I,O,P}(\theta, \delta)), \\
\text{rng}_{I,O,P}(\theta, \delta) &= \text{rng}_{I,O,P}(\text{dom}_{I,O,P}(\theta, \delta), \delta) = \text{rng}_{I,O,P}(\theta, \text{rng}_{I,O,P}(\theta, \delta)).
\end{align*}
\]

Proof sketch: By induction on the recursive definition of $\text{dom}_{I,O,P}$ and $\text{rng}_{I,O,P}$. \hfill \square

Definition 6 (Privacy preserving) A function $f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*])$ is called privacy preserving with respect to the initial wiring $(I, O)$ and the private names $P$ iff:

\[
\forall \theta : f(\theta) = f(\text{dom}_{I,O,P}(\theta, f(\theta))) = \text{rng}_{I,O,P}(\theta, f(\theta)).
\]

Definition 7 (Mobile functions) A function $f \in (N \rightarrow [N^*]) \rightarrow (N \rightarrow [N^*])$ is said to be mobile with respect to $(I, O, P)$, where $I \cap O = P \cap (I \cup O) = \emptyset$, if it is strongly pulse-driven and privacy preserving. We use the arrow $I,O,P$ to distinguish functions that are mobile with respect to $(I, O, P)$ from other functions. \hfill \square

4 Mobile Components

We model a nondeterministic component by a set of mobile functions $F$. Any pair $(\theta, f(\theta))$, where $f \in F$, is a possible behavior of the component. Intuitively, for each input history each mobile function $f \in F$ represents one possible nondeterministic behavior.

Different sets of mobile functions may have the same set of behaviors. The reason is that for some sets of mobile functions we may find additional mobile functions which can be understood as combinations of the functions already in the set. For example, we may find a mobile function $g$ which for one input history behaves as the function $f \in F$ and for an other input history behaves as the function $f' \in F$, and so on. This means, a model in which a nondeterministic component is represented by an arbitrary set of mobile functions, is too distinguishing, and consequently, not fully abstract. To achieve full abstraction we consider only closed sets, i.e. sets $F$, where each combination of functions in $F$, which gives a mobile function, is also in $F$.

Definition 8 (Mobile components) A mobile component, with initial wiring $(I, O)$ and private names $P$, where $P \cap (I \cup O) = \emptyset$, is modeled by a nonempty set of mobile functions

\[
F \subseteq (N \rightarrow [M^*])^{I,O,P} (N \rightarrow [M^*])
\]

that is closed in the sense that for any mobile function $f$ of the same signature

\[
(\forall \theta \in (N \rightarrow [M^*]) : \exists f' \in F : f(\theta) = f'(\theta)) \Rightarrow f \in F.
\]

\hfill \square
5 Composition

Definition 9 (Point-to-point composition) Given two mobile components:

\[ F_1 \subseteq (\nu : N \rightarrow [M^s])^I_1, O_1, P_1 (N \rightarrow [M^s]), \quad F_2 \subseteq (\nu : N \rightarrow [M^s])^I_2, O_2, P_2 (N \rightarrow [M^s]) \]

such that \( I_1 \cap O_1 = I_2 \cap O_2 = I_1 \cap I_2 = O_1 \cap O_2 = \emptyset \),
\( P_1 \cap (I_2 \cup O_2 \cup P_2) = P_2 \cap (I_1 \cup O_1 \cup P_1) = \emptyset \). The composition of \( F_1 \) and \( F_2 \) gives a network whose static structure is characterized by Figure 3. It is formally defined as follows:

\[ I = (I_1 \setminus O_2) \cup (I_2 \setminus O_1), \quad O = (O_1 \setminus I_2) \cup (O_2 \setminus I_1), \]
\[ IO = (I_1 \cap O_2) \cup (I_2 \cap O_1), \quad P = P_1 \cup P_2 \cup IO \]

\[ F_1 \otimes F_2 = \{ f \in (\nu : N \rightarrow [M^s])^{I, O, P} (N \rightarrow [M^s]) \mid \forall \theta : \exists f_1 \in F_1, f_2 \in F_2 : \]
\[ f(\theta) = \text{rng}_{I, O, P}(\theta, \varphi + \psi) \quad \text{where} \]
\[ \varphi = f_1(\vartheta + \psi), \quad \psi = f_2(\vartheta + \varphi), \quad \vartheta = \text{dom}_{I, O, P}(\theta, \varphi + \psi) \] \( \square \)

Note the role of \( \text{dom}_{I, O, P} \) and \( \text{rng}_{I, O, P} \) in maintaining privacy. If \( F_1 \) sends a private port \( !o \) on a feedback channel, then only \( F_2 \) should send along \( o \) and only \( F_1 \) should receive on \( o \). \( F_1 \) can receive on \( o \) because \( \text{dom}_{I_1, O_1, P_1} \) is automatically enlarged with \( o \). Only \( F_1 \) can receive on \( o \) because \( \text{rng}_{I_1, O_1, P_1} \) automatically hides what \( F_2 \) sends along \( o \). \( F_2 \) can send along \( o \) because \( \text{rng}_{I_2, O_2, P_2} \) is automatically enlarged with \( o \). Only \( F_2 \) can influence \( F_1 \) on \( o \) because \( \text{dom}_{I_1, O_1, P_1} \) automatically hides what the environment sends along \( o \).

Similarly, if \( F_1 \) sends a private port \( ?i \) on a feedback channel, then only \( F_2 \) should receive on \( i \) and only \( F_1 \) should send along \( i \). \( F_2 \) can receive on \( i \) because \( \text{dom}_{I_2, O_2, P_2} \) is automatically enlarged with \( i \). Only \( F_2 \) can receive on \( i \) because \( \text{rng}_{I_2, O_2, P_2} \) automatically hides what \( F_1 \) sends along \( i \). \( F_1 \) can send along \( i \) because \( \text{rng}_{I_1, O_1, P_1} \) is automatically enlarged with \( i \). Only \( F_1 \) can influence \( F_2 \) on \( i \) because \( \text{dom}_{I_1, O_1, P_1} \) automatically hides what the environment sends along \( i \).

Theorem 5 \( F_1 \otimes F_2 \) is a mobile component.

Proof: See appendix. \( \square \)
6 Communication Central

As an example we specify a communication central (see Figure 4). Its task is to build up connections between station\(_1\) to station\(_n\). Each station\(_k\) is connected to the central with an output channel \(o_k\) and an input channel \(i_k\). These are the initial “wires”. Along their output channel \(o\), the stations can send ports to be connected (both read and write) to the central which according to an internal prophecy distributes them to the other stations.

Let \(!c\) be a write port sent by station\(_1\) to the central, which forwards it to station\(_2\). Then station\(_2\) can send along the channel \(c\) and station\(_1\) can receive on the channel \(c\). Hence, these two stations are dynamically connected.

![Diagram](attachment:communication_central_diagram.png)

In order to specify the central, let us introduce two basic operators. The first operator is a filtration operator for tuples of streams. For any set of \(n\)-tuples of messages \(A\) and \(n\)-tuple of streams \(s\) by \(A \odot s\) we denote the result of truncating each stream in \(s\) at the length of the shortest stream in \(s\), and selecting or deleting \(s_j\) depending on whether \(s_j\) is in \(A\) or not. By \(s_j\) we denote the tuple of messages whose \(k\th\) component is equal to the \(j\th\) message of the \(k\th\) component stream of \(s\). For example,

\[
\{(a, a)\} \odot \{(a, b, b, a, b, a), (a, a, a)\} = (\{a, a\}, \{a, a\}).
\]

The second operator is a time abstraction operator: for any named communication history \(\beta, \overline{\beta}\) denotes the result of removing all time information in \(\beta\). For any \(i\), this is achieved by concatenating all the finite streams in \(\beta(i)\) into one stream\(^3\). Thus each communication history consisting of infinitely many finite streams of messages is replaced by the result of concatenating its finite streams into one stream of messages. As a result the timing information is abstracted away.

\[
\text{central} \overset{\text{def}}{=} \{ f \in (N \xrightarrow{u} [M^\omega]) : \{o_1, \ldots, o_n\}, \{i_1, \ldots, i_n\}, \theta \in (N \xrightarrow{u} [M^\omega]) \mid \forall \theta : R(\overline{\theta}, f(\overline{\theta})) \},
\]

where

\[
R(\alpha, \beta) \overset{\text{def}}{=} \exists p_{\text{in}}, p_{\text{out}} \in \{1, \ldots, n\}, \exists \text{int_buf} : M^\omega : \forall j \in [1..n] : \]

\[
\alpha(o_j) = (M \times \{j\}) \odot (\text{int_buf}, p_{\text{in}}) \wedge \\
\beta(i_j) = (M \times \{j\}) \odot (\text{int_buf}, p_{\text{out}}).
\]

Note that this specification does not say anything about the timing of the output. The existentially quantified variable \(\text{int_buf}\) can be understood as an internal buffer in which

\(^3\)Do not confuse the time abstraction operator with set difference.
the input messages are placed in accordance with the oracle $p_{in}$. The other oracle $p_{out}$ characterizes the way these messages are distributed to the stations.

7 Discussion

We have had several sources of inspiration. First of all, the modeling of nondeterministic networks is inspired by the semantic models for static nondeterministic networks [Par83], [Kok87], [Bro87]. Park models components by sets of functions in the same way as we do. However, he models time with time ticks $\sqrt{}$ and his functions are defined also for finite streams. Moreover, infinite streams are not required to have infinitely many ticks. Kok models nondeterministic components by functions mapping communication histories to sets of communication histories. We use instead a closed set of deterministic pulse-driven functions. This allows us to model unbounded nondeterminism without having to introduce a more complex metric. [Bro87] employs sets of functions as we do, but these functions work on untimed finite and infinite streams. This makes the model more abstract, but at the same time more complex with respect to its theoretical basis. The formulation of pulse-drivenness has been taken from [Bro95a], and the use of named communication histories is based on [BD92].

Our ideas on mobility have also had several sources. [Bro95b] and [Gro94] give an equational characterization of dynamic reconfiguration. [Gro94] also presents a semantic model for mobile, deterministic networks. However, that model is higher-order and mobility is achieved by communicating channels and functions instead of ports.

The idea of communicating names (ports) was inspired by [MPW92a, MPW92b]. The action structures [Mil92] are also related to our model. The idea of associating an access right with each channel in order to control interference was taken from [SKL90]. The semantic model of [SRP91] has also some similarities to our model. However, the intentions are complementary. [SRP91] aims at generality. We, on the other hand, have developed a particular model based on traditional stream processing functions. In [SRP91] inconsistencies can only be avoided by syntactic constraints. In our model inconsistencies cannot occur.

A Streams and Named Stream Tuples

A stream is a finite or infinite sequence of elements. For any set of elements $E$, we use $E^*$ to denote the set of all finite streams over $E$, and $[E]$ to denote the set of all infinite streams over $E$. For any infinite stream $s$, we use $s[j]$ to denote the prefix of $s$ containing exactly $j$ elements. We use $\epsilon$ to denote the empty stream.

We define the metric of infinite streams generically with respect to an arbitrary discrete metric $(E, \rho)$.

A Streams and Named Stream Tuples

A stream is a finite or infinite sequence of elements. For any set of elements $E
Definition 10 (The metric of infinite streams) The metric of infinite streams 
([E], d) over a discrete metric (E, ρ) is defined as follows:
\[ [E] = \prod_{i \in \mathbb{N}} E \]
\[ d(s, t) = \inf \{2^{-j} \mid s_j = t_j\} \]

This metric is also known as the Baire metric [Eng77].

Theorem 6 The metric space of streams ([E], d) is complete.

Proof sketch: See for example [Eng77].

A named stream tuple is a mapping θ ∈ (I → [E]) from a set of names to infinite streams. ↓ is overloaded to named stream tuples in a point-wise style, i.e. θ↓j denotes the result of applying ↓j to each component of θ.

Definition 11 (The metric of named stream tuples) The metric of named stream 
tuples (I → [E], d) with names in I and elements in (E, ρ) is defined as follows:
\[ I \to [E] \text{ is the set of functions from the countable set I to the metric } [E], \]
\[ d(s, t) = \inf \{2^{-j} \mid s_j = t_j\} \]

Theorem 7 The metric space of named stream tuples (I → [E], d) is complete.

Proof sketch: This metric is equivalent to the Cartesian product metric \( \prod_{i \in I} [E] \) which is complete because [E] is [Eng77].

B Metric Space Definitions

B.1 Metric Space Basics

The fundamental concept in metric spaces is the concept of distance.

Definition 12 (Metric Space) A metric space is a pair (D, d) consisting of a nonempty 
set D and a mapping d ∈ D × D → R, called a metric or distance, which has the following 
properties:

1. \( \forall x, y \in D : \quad d(x, y) = 0 \iff x = y \)
2. \( \forall x, y \in D : \quad d(x, y) = d(y, x) \)
3. \( \forall x, y, z \in D : \quad d(x, y) \leq d(x, z) + d(z, y) \)
A very simple example of a metric is the discrete metric.

**Definition 13 (The discrete metric)** The discrete metric \((D, d)\) over a set \(D\) is defined as follows:

\[
d(x, y) = \begin{cases} 
0 & \text{if } x = y \\
1 & \text{if } x \neq y
\end{cases}
\]

Measuring the distance between the elements of a sequence \((x_i)_{i \in \mathbb{N}}\) in \(D\) we obtain the familiar definitions for convergence and limits.

**Definition 14 (Convergence and limits)** Let \((D, d)\) be a metric space and let \((x_i)_{i \in \mathbb{N}}\) be a sequence in \(D\).

1. We say that \((x_i)_{i \in \mathbb{N}}\) is a Cauchy sequence whenever we have:
   \[
   \forall \epsilon > 0 : \exists N \in \mathbb{N} : \forall n, m > N : d(x_n, x_m) < \epsilon.
   \]
2. We say that \((x_i)_{i \in \mathbb{N}}\) converges to \(x \in D\) denoted by \(x = \lim_{n \to \infty} x_i\) and call \(x\) the limit of \((x_i)_{i \in \mathbb{N}}\) whenever we have:
   \[
   \forall \epsilon > 0 : \exists N \in \mathbb{N} : \forall n > N : d(x_n, x) < \epsilon.
   \]
3. The metric space \((D, d)\) is called complete whenever each Cauchy sequence converges to an element of \(D\).

**Theorem 8** The discrete metric is complete.

**Proof sketch:** Each Cauchy sequence is constant from a given \(N\).

A very important class of functions over metric spaces is the class of Lipschitz functions.

**Definition 15 (Lipschitz functions)** Let \((D_1, d_1)\) and \((D_2, d_2)\) be metric spaces and let \(f \in D_1 \to D_2\) be a function. We call \(f\) Lipschitz function with constant \(c\) if there is a constant \(c \geq 0\) such that the following condition is satisfied:

\[
d(f(x), f(y)) \leq c \cdot d(x, y)
\]

For a function \(f\) with arity \(n\) the above condition generalizes to:

\[
d(f(x_1, \ldots, x_n), f(y_1, \ldots, y_n)) \leq c \cdot \max\{d(x_i, y_i) \mid i \in [1..n]\}
\]

If \(c = 1\) we call \(f\) non-expansive. If \(c < 1\) we call \(f\) contractive.

**Theorem 9** The composition of two Lipschitz functions \(f \in D_1 \to D_2\) and \(g \in D_2 \to D_3\) is a Lipschitz function with constant \(c_1 \cdot c_2\).
Proof sketch: \[ \delta(g(f(x_1)), g(f(x_2))) \leq c_2 \cdot \delta(f(x_1), f(x_2)) \leq c_2 \cdot c_1 \cdot \delta(x_1, x_2) \]

Lemma 1 The composition of a contractive and a non-expansive function is contractive. The composition of two non-expansive functions is non-expansive. Identity is non-expansive.

The main tool for handling recursion in metric spaces is the Banach's fix-point theorem. It guarantees the existence of a unique fix-point for every contractive function.

Theorem 10 (Banach's fix-point theorem) Let \((D, d)\) be a complete metric space and \(f : D \to D\) a contractive function. Then there exists an \(x \in D\), such that the following holds:

1. \(x = f(x)\) (\(x\) is a fix-point of \(f\))
2. \(\forall y \in D : y = f(y) \Rightarrow y = x\) (\(x\) is unique)
3. \(\forall z \in D : x = \lim_{n \to \infty} f^n(z)\) where
   \[ f^0(z) = z \quad f^{n+1}(z) = f(f^n(z)) \]

Proof sketch: See [Eng77] or [Sut75].

Usually we want to use a parameterized version of this theorem.

Definition 16 (Parameterized fix-point) Let \(f : D \times D_1 \times \ldots \times D_n \to D\) be a function of non-empty complete metric spaces that is contractive in its first argument. We define the parameterized fix-point function \(\mu f\) as follows:

\( (\mu f) \in D_1 \times \ldots \times D_n \to D \)
\( (\mu f)(y_1, \ldots, y_n) = x \)

where \(x\) is the unique element of \(D\) such that \(x = f(x, y_1, \ldots, y_n)\) as guaranteed by Banach's fix-point theorem.

Theorem 11 If \(f\) is contractive (non-expansive) so is \(\mu f\).

C Full Abstraction

The context free syntax of a data-flow network is given by

\[\text{net ::= n | net } \times \text{ net}\]
where $n$ is a basic component. Network terms defined in this way are also called *rough terms*, because they do not contain information about their syntactic interface $(I, O, P)$. By adding this interface information and the formation constraints of Section 5, we obtain the *context sensitive syntax*.

A context $C(.) ::= (N \xrightarrow{u} [M^*]) \xrightarrow{L_{I,O,P}} (N \xrightarrow{u} [M^*])$ is a network with exactly one hole of type $(N \xrightarrow{u} [M^*]) \xrightarrow{L_{I,O,P}} (N \xrightarrow{u} [M^*])$. A network of this type is allowed to be substituted for the hole.

Given that each basic component can be understood as a mobile component as defined above, then the semantics of a network expression follows straightforwardly from the definition in Section 5. Let us denote this semantics by $D$. We define the observation semantics of a network as the corresponding input/output behavior:

$$\mathcal{O}[n] = \{ (x, y) \mid \exists f \in D[n] : y = f(x) \}$$

Now, we define full abstraction as in [Jon89].

**Definition 17 (Full abstraction)** The model $D$ is said to be fully abstract with respect to $\mathcal{O}$ if for all networks $n, m :: (N \xrightarrow{u} [M^*]) \xrightarrow{L_{I,O,P}} (N \xrightarrow{u} [M^*])$

1. $D[n] = D[m] \Rightarrow \mathcal{O}[n] = \mathcal{O}[n]$ \{ $D$ is more distinguishing\}
2. $\forall C(.) : D[n] = D[m] \Rightarrow D[C(n)] = D[C(m)]$ \{ $D$ is compositional\}
3. $D[n] \neq D[m] \Rightarrow \exists C(.) : \mathcal{O}[C(n)] \neq \mathcal{O}[C(m)]$ \[ \square \]

**Theorem 12** $D$ is fully abstract with respect to $\mathcal{O}$.

**Proof sketch:** Property (1) follows from the definition of $\mathcal{O}$. Property (2) follows by construction. To prove Property (3), suppose $D[n] \neq D[m]$. This means, there is an $f$ which is contained in the first set, but not in the second. Since $D[m]$ is closed, there is a $\theta$ such that $\forall g \in D[m] : f(\theta) \neq g(\theta)$. Otherwise, closedness would require that $f$ is also in $D[m]$. As a consequence $f(\theta) \not\in \mathcal{O}[m]$. Hence, $\mathcal{O}[n] \neq \mathcal{O}[m]$ \[ \square \]

Note that the full abstraction property is lost if the components are not required to be closed.

**D Proof**

We now prove that $F_1 \otimes F_2$ is a mobile component. The proof is split into several steps. Let

$$F_1 \otimes F_2 = \{ f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*]) \mid \forall \theta : \exists f_1 \in F_1, f_2 \in F_2 : f(\theta) = \text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) \text{ where} \varphi = f_1(\partial \leftrightarrow \psi), \psi = f_2(\vartheta \leftrightarrow \varphi), \vartheta = \text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) \}$$
Lemma 1 \( F_1 \odot F_2 \neq \emptyset \).

**Proof:** Since \( F_1 \) and \( F_2 \) are mobile components we may find functions \( f_1, f_2 \) such that \( f_1 \in F_1 \) and \( f_2 \in F_2 \). Based on these functions we construct a function \( f \) which is strongly pulse-driven, generic and satisfies the recursive definition above.

Let

\[
g \in \left((N \rightarrow [M^*]) \times (N \rightarrow [M^*]) \times (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*]) \times (N \rightarrow [M^*])\right)
\]

\[
g((\varphi, \psi), \theta) = (f_1(\vartheta \leftrightarrow \psi), f_2(\vartheta \leftrightarrow \varphi)) \quad \text{where} \quad \vartheta = \text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi).
\]

Theorem 9 (in the appendix) and the way \( g \) is defined in terms of strongly and weakly pulse-driven functions imply that \( g \) is strongly pulse-driven. Thus \( \mu g \) is well-defined, in which case Theorem 11 (in the appendix) implies that \( \mu g \) is strongly pulse-driven. Let

\[
f \in (N \rightarrow [M^*]) \rightarrow (N \rightarrow [M^*])
\]

\[
f(\theta) = \text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) \quad \text{where} \quad (\varphi, \psi) = (\mu g)(\theta).
\]

Theorem 9 and the way \( f \) is defined in terms of strongly and weakly pulse-driven functions imply that \( f \) is strongly pulse-driven.

Finally, since \( \exists f_1, f_2 : \forall \theta : P \) implies \( \forall \theta : \exists f_1, f_2 : P \) it follows that \( f \in F_1 \odot F_2 \). \( \square \)

Lemma 2 \( F_1 \odot F_2 \) is generic.

**Proof:** That \( f \) is generic is a consequence of the next two propositions.

**Proposition 1** \( f(\theta) = f(\text{dom}_{I,O,P}(\theta, f(\theta))) \).

**Proof:** First, note that \( f(\theta) = f(\text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi)) \) because

\[
\text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) = \text{rng}_{I,O,P}(\text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi), \varphi \leftrightarrow \psi) \quad \text{by Theorem 4}
\]

\[
\vartheta = \text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) = \text{dom}_{I,O,P}(\text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi), \varphi \leftrightarrow \psi) \quad \text{by Theorem 4.}
\]

Now

\[
f(\text{dom}_{I,O,P}(\theta, f(\theta))) =
\]

\[
f(\text{dom}_{I,O,P}(\theta, \text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi))) = \{\text{by definition of } f\}
\]

\[
f(\text{dom}_{I,O,P}(\theta, \varphi \leftrightarrow \psi)) = \{\text{by Theorem 4}\}
\]

\[
f(\theta) \quad \{\text{by above remark}\}
\]

\( \square \)

**Proposition 2** \( f(\theta) = \text{rng}_{I,O,P}(\theta, f(\theta)) \).

**Proof:**

\[
\text{rng}_{I,O,P}(\theta, f(\theta)) =
\]

\[
\text{rng}_{I,O,P}(\theta, \text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi)) = \{\text{by definition of } f\}
\]

\[
\text{rng}_{I,O,P}(\theta, \varphi \leftrightarrow \psi) = \{\text{by Theorem 4}\}
\]

\[
f(\theta) \quad \{\text{by definition of } f\}
\]

\( \square \)

\( \square \)

**Lemma 3** If \( \theta \in N \xrightarrow{u} [M^*] \) then \( \leftrightarrow \) can be replaced by \( + \) in the definition of \( \odot \). Moreover \( \varphi \leftrightarrow \psi, \vartheta \leftrightarrow \psi, \vartheta \leftrightarrow \varphi \in N \xrightarrow{u} [M^*] \).
Proof: Let

\[ ep_n^1 = ep_{I_0,P_0}(\theta \leftrightarrow \psi, \varphi)(n), \quad pp_n^1 = pp_{I_0,P_0}(\theta \leftrightarrow \psi, \varphi)(n), \]

\[ ep_n^2 = ep_{I_2,P_2}(\theta \leftrightarrow \psi, \varphi)(n), \quad pp_n^2 = pp_{I_2,P_2}(\theta \leftrightarrow \psi, \varphi)(n), \]

\[ ep_n = ep_{I_0,P}(\theta, \varphi \leftrightarrow \psi)(n), \quad pp_n = pp_{I_0,P}(\theta, \varphi \leftrightarrow \psi)(n). \]

Proposition 3 If \( \theta \in N \overset{u}{\rightarrow} [M^*] \) then \( \varphi, \psi, \theta \leftrightarrow \psi, \theta \leftrightarrow \varphi \in N \overset{u}{\rightarrow} [M^*] \) and for all \( n \)

\[ ep_n^1 \cap pp_n^1 = ep_n^2 \cap pp_n^2 \]

\[ (pp_n^1 \cup ep_n^1) \cap (pp_n^2 \cup ep_n^2) = \emptyset, \]

\[ ep_n = (ep_n^1 \setminus \overline{ep_n^2}) \cup (ep_n^2 \setminus \overline{ep_n^1}) \]

\[ pp_n = (ep_n^1 \cap ep_n^2) \cup (ep_n^2 \cap ep_n^1) \cup pp_n^1 \cup pp_n^2 \]

Proof: Suppose the above equalities are our induction hypothesis.

Base case:

\[ pp_1 = \, \exists ! P_1, \quad pp_2 = \, \exists ! P_2, \quad pp_1 = \, \exists !(P_1 \cup P_2 \cup IO), \]

\[ ep_1 = \, \exists ! I_1 \cup O_1, \quad ep_2 = \, \exists ! I_2 \cup O_2, \quad ep_1 = \, \exists ! I \cup O, \]

\[ ep_1 = \, \exists ! I_1 \cup O_1, \quad ep_2 = \, \exists ! I_2 \cup O_2. \]

These values clearly satisfy the above equations for \( n = 1 \). Together with the port-unicity preserving property of \( f_1 \) and \( f_2 \) they also assure the port unicity of \( \varphi, \psi, \theta \leftrightarrow \psi, \theta \leftrightarrow \varphi \) and \( \varphi \leftrightarrow \psi \) for \( n = 1 \).

Induction step: Expanding the definitions of \( ep \) and \( pp \) we obtain

\[ ep_{n+1}^1 = (ep_n^1 \cup r_n^1 \cup g_n^1) \setminus (s_n^1 \cup h_n^1), \quad pp_{n+1}^1 = (pp_n^1 \cup h_n^1) \setminus (s_n^1 \cup \overline{s_n^1}), \]

\[ ep_{n+1}^2 = (ep_n^2 \cup r_n^2 \cup g_n^2) \setminus (s_n^2 \cup h_n^2), \quad pp_{n+1}^2 = (pp_n^2 \cup h_n^2) \setminus (s_n^2 \cup \overline{s_n^2}), \]

\[ ep_{n+1} = (ep_n \cup r_n \cup g_n) \setminus (s_n \cup h_n), \quad pp_{n+1} = (pp_n \cup h_n) \setminus (s_n \cup \overline{s_n}) \]

where

\[ r_n^1 = \bigcup_{i \in \text{ep}_n^1} \{ c \mid c \in \text{pp}_n^1 \cup \text{ep}_n^1 \cap (\theta \leftrightarrow \psi)(i)(n) \}, \quad h_n^1 = \{ c, \bar{c} \mid c \in r_n^1 \land \bar{c} \in \text{ep}_n^1 \} \]

\[ r_n^2 = \bigcup_{i \in \text{ep}_n^2} \{ c \mid c \in \text{pp}_n^2 \cup \text{ep}_n^2 \cap (\theta \leftrightarrow \varphi)(i)(n) \}, \quad h_n^2 = \{ c, \bar{c} \mid c \in r_n^2 \land \bar{c} \in \text{ep}_n^2 \} \]

\[ r_n = \bigcup_{i \in \text{ep}_n} \{ c \mid c \in \text{pp}_n \cup \text{ep}_n \cap \theta(i)(n) \}, \quad h_n = \{ c, \bar{c} \mid c \in r_n \land \bar{c} \in \text{ep}_n \} \]

\[ s_n^1 = \bigcup_{i \in \text{ep}_n^1} \{ c \mid c \in (\text{pp}_n^1 \cup \text{ep}_n^1) \cap \varphi(i)(n) \}, \quad g_n^1 = \{ \bar{c} \mid c \in s_n^1 \land c \in \text{pp}_n^1 \} \]

\[ s_n^2 = \bigcup_{i \in \text{ep}_n^2} \{ c \mid c \in (\text{pp}_n^2 \cup \text{ep}_n^2) \cap \varphi(i)(n) \}, \quad g_n^2 = \{ \bar{c} \mid c \in s_n^2 \land c \in \text{pp}_n^2 \} \]

\[ s_n = \bigcup_{i \in \text{ep}_n} \{ c \mid c \in (\text{pp}_n \cup \text{ep}_n) \cap (\varphi \leftrightarrow \psi)(i)(n) \}, \quad g_n = \{ \bar{c} \mid c \in s_n \land c \in \text{pp}_n \} \]

We do now a case analysis which corresponds to each term of the above expressions.

1. **External Input**: \( ?i \in \text{ep}_n^1 \cap \text{ep}_n \)

   By the induction hypothesis \( ?i \not\in \overline{\text{ep}_n^2} \). As a consequence \( (\theta \leftrightarrow \psi)(i)(n) = \theta(i)(n) \). Suppose \( c \in \theta(i)(n) \). Clearly \( c \in \text{ep}_n \cup \text{pp}_n \). There are two cases \( \bar{c} \not\in \text{ep}_n^1 \) and \( c \in \text{ep}_n^1 \):

   \[ \bar{c} \not\in \text{ep}_n^1 \]

   \[ c \in r_n^1, \quad \{ \text{by definition} \} \]

   \[ c \not\in h_n, \quad \{ \text{by definition} \} \]

   \[ c \not\in s_n^1, \quad \{ (\text{ep}_n^1 \cup \text{pp}_n^1) \cap \text{ep}_n \cup \text{pp}_n = \emptyset \} \]

   \[ \text{pp}_n = \text{pp}_{I_0,P}(\theta, \varphi \leftrightarrow \psi)(n). \]
Hence $c \in \text{ep}_{n+1}^1$ and $c \not\in \text{pp}_{n+1}^1$.

\[ c \not\in \text{ep}_{n+1}^2, \quad \{ \text{ep}_{n+1}^2 \cap \text{ep}_{n+1}^1 \cup \text{pp}_{n+1} = \emptyset \} \]
\[ c \not\in \text{r}_{n+1}^2, \quad \{ u(\theta), \quad \{ \text{ep}_{1}^1 \cup \text{pp}_{n+1}^1 \} \cap \text{ep}_{n+1}^1 \cup \text{pp}_{n+1} = \emptyset \} \]
\[ c \not\in \text{s}_{n+1}^2, \quad \{ (\text{ep}_{n+1}^2 \cup \text{pp}_{n+1}^2) \cap \text{ep}_{n+1}^1 \cup \text{pp}_{n+1} = \emptyset \} \]

Hence $c \not\in \text{ep}_{n+1}^2$ and $c \not\in \text{pp}_{n+1}^2$.

\[ c \in r_{n+1}^1, \quad \{ \text{by definition} \} \]
\[ c \in h_{n+1}^1, \quad \{ \text{by definition} \} \]
\[ c \not\in s_{n+1}^1, \quad \{ (\text{ep}_{1}^1 \cup \text{pp}_{n+1}^1) \cap \text{ep}_{n+1}^1 \cup \text{pp}_{n+1} = \emptyset \} \]

Hence $c \not\in \text{ep}_{n+1}^1$ and $c \in \text{pp}_{n+1}^1$. For $f_2$ nothing changes. Hence $c \not\in \text{ep}_{n+1}^2$ and $c \not\in \text{pp}_{n+1}^2$.

\[ c \in r_{n+1}^1, \quad \{ \text{by definition} \} \]
\[ c \in h_{n+1}^1, \quad \{ \text{by definition} \} \]
\[ c \not\in s_{n+1}^1, \quad \{ (\text{ep}_{n+1}^2 \cup \text{pp}_{n+1}^2) \cap \text{ep}_{n+1}^1 \cup \text{pp}_{n+1} = \emptyset \} \]

Hence $c \not\in \text{ep}_{n+1}^2$ and $c \in \text{pp}_{n+1}^2$.

In both cases all the above equations are satisfied. Moreover, the port-unicity of $\vartheta \leftrightarrow \psi$ and $\vartheta \leftrightarrow \varphi$ at time $n$, and the port-unicity preserving property of $f_1$ and $f_2$ implies the port-unicity of $\varphi$ and $\psi$ at time $n+1$. Then the above disjointness equations imply the unicity of $\vartheta \leftrightarrow \psi$, $\vartheta \leftrightarrow \psi$ and $\varphi \leftrightarrow \psi$ at time $n+1$.

2. Internal Input: $i \in \text{ep}_{n}^1 \cap \text{ep}_{n}^2$

By induction hypothesis $i \not\in \text{ep}_{n}^1$. Hence $(\vartheta \leftrightarrow \psi)(i)(n) = \psi(i)(n)$. Suppose $c \in \psi(i)(n)$. Then there are two disjoint cases: $c \in \text{ep}_{n}^2$ or $c \in \text{pp}_{n}^2$.

\[ c \in \text{ep}_{n}^2 \]
\[ c \in \text{r}_{n}^1, \quad \{ \text{by definition} \} \]
\[ c \not\in \text{h}_{n}, \quad \{ a. \ c \not\in \text{ep}_{n}^1 \} \]
\[ c \in \text{h}_{n}, \quad \{ b. \ c \in \text{ep}_{n}^1 \} \]
\[ c \not\in \text{s}_{n}^1, \quad \{ (\text{ep}_{n}^1 \cup \text{pp}_{n}^1) \cap \text{ep}_{n}^1 = \emptyset \} \]

Hence $c \in \text{ep}_{n+1}^1$ and $c \not\in \text{pp}_{n+1}^1$ in case $a$ or $c \not\in \text{ep}_{n+1}^1$ and $c \in \text{pp}_{n+1}^1$ in case $b$.

\[ c \not\in \text{r}_{n}^2, \quad \{ \text{ep}_{n}^2 \cap (\text{ep}_{n}^1 \cup \text{pp}_{n}^1) = \text{ep}_{n}^2 \cap \text{ep}_{n}^1 = \emptyset \} \]
\[ c \not\in \text{s}_{n}^2, \quad \{ \text{by definition} \} \]
\[ c \not\in \text{g}_{n}^2, \quad \{ \text{ep}_{n}^2 \cap \text{pp}_{n}^2 = \emptyset \} \]

Hence $c \not\in \text{ep}_{n+1}^2$ and $c \not\in \text{pp}_{n+1}^2$. 

21
c \in \text{ep}_n \land c \not\in \text{pp}_n, \quad \{a. \bar{c} \not\in \text{ep}_n\}
\begin{align*}
c \not\in \text{ep}_n \land c \in \text{pp}_n & \quad \{b. \bar{c} \in \text{ep}_n\} \\
c \not\in r_n, & \quad \{\text{ep}_n^2 \cap \text{ep}_n \cup \text{pp}_n = \emptyset\} \\
c \not\in s_n, & \quad \{u(\psi), \ (\text{ep}_n^1 \cup \text{pp}_n^1) \cap \text{pp}_n^2 = \emptyset\}
\end{align*}
Hence $c \in \text{ep}_{n+1}$ and $c \not\in \text{pp}_{n+1}$ in case $a$ or $c \not\in \text{ep}_{n+1}$ and $c \in \text{pp}_{n+1}$ in case $b$.

c \in \text{pp}_n^2
\begin{align*}
c \in r_n^1 & \quad \{\text{by definition}\} \\
c \not\in h_n^1 & \quad \{c, \bar{c} \not\in \text{ep}_n^1\} \\
c \not\in s_n^1, & \quad \{(\text{ep}_n^1 \cup \text{pp}_n^1) \cap \text{pp}_n^2 = \emptyset\}
\end{align*}
Hence $c \in \text{ep}_{n+1}^1$ and $c \not\in \text{pp}_{n+1}^1$.

c \not\in r_n^2 \\
c \in s_n^2, & \quad \{\text{by definition}\} \\
\bar{c} \in g_n^2, & \quad \{\text{by definition}\}
Hence $c \not\in \text{ep}_{n+1}^2$ and $c \not\in \text{pp}_{n+1}^2$, and $\bar{c} \in \text{ep}_n^2$.
\begin{align*}
c \not\in \text{ep}_n & \quad \{\text{pp}_n^2 \cap \text{ep}_n = \emptyset\} \\
c \in \text{pp}_n & \quad \{\text{induction hypothesis}\} \\
c \not\in r_n & \quad \{\text{pp}_n^2 \cap \text{ep}_n \cup \text{pp}_n = \emptyset\} \\
c \not\in s_n, & \quad \{u(\psi), \ (\text{ep}_n^1 \cup \text{pp}_n^1) \cap \text{pp}_n^2 = \emptyset\}
\end{align*}
Hence $c \not\in \text{ep}_{n+1}$ and $c \in \text{pp}_{n+1}$.

It is easy to show that all the above equations hold. Moreover, a similar argument as before, proves the port-unicity.

3. External Output: $!i \in \text{ep}_n^1 \cap \text{ep}_n$

By the induction hypothesis $!i \not\in \text{ep}_n^2$. The only interesting case is if $c \in \varphi(i)(n)$ is private and its complement is not sent, i.e., if $c \in \text{pp}_n$ and $\bar{c} \not\in \varphi(i)(n)$.

\begin{align*}
c \in s_n^1, & \quad \{\text{by definition}\} \\
\bar{c} \in g_n^1, & \quad \{\text{by definition}\}
\end{align*}
Hence $\bar{c} \in \text{ep}_{n+1}^1$ and $c, \bar{c} \not\in \text{pp}_{n+1}^1$.
\begin{align*}
c \not\in \text{ep}_n^2 & \quad \{\text{pp}_n^1 \cap \text{ep}_n^2 = \emptyset\} \\
c, \bar{c} \not\in r_n^2, & \quad \{u(\varphi), \ \text{pp}_n^1 \cap \text{ep}_n \cup \text{pp}_n = \emptyset\} \\
c, \bar{c} \not\in s_n^2, & \quad \{\text{pp}_n^1 \cap (\text{ep}_n^1 \cup \text{pp}_n^1) = \emptyset\}
\end{align*}
Hence $c, \bar{c} \not\in \text{ep}_{n+1}^2$ and $c, \bar{c} \not\in \text{pp}_{n+1}^2$.
\begin{align*}
c \in s_n, & \quad \{\text{by definition}\} \\
\bar{c} \in g_n, & \quad \{\text{by definition}\}
\end{align*}
Hence $\bar{c} \in \text{ep}_{n+1}$ and $c, \bar{c} \not\in \text{pp}_{n+1}$.

It is easy to show that all the above equations hold. Moreover, a similar argument as before, proves the port-unicity.
4. Internal Output: \( !i \in \text{ep}_n^1 \cap \text{ep}_n^2 \)

By the induction hypothesis \( !i \not\in \text{ep}_n \). The only interesting case is if \( c \in \varphi(i)(n) \) is private and its complement is not sent, i.e., if \( c \in \text{pp}_n^1 \) and \( \bar{c} \not\in \varphi(i)(n) \).

\[
\begin{align*}
  c & \in s_n^1, & \{ \text{by definition} \} \\
  \bar{c} & \in g_n^1, & \{ \text{by definition} \}
\end{align*}
\]

Hence \( \bar{c} \in \text{ep}_{n+1}^1, c \not\in \text{ep}_{n+1}^1 \) and \( c, \bar{c} \not\in \text{pp}_{n+1}^1 \).

\[
\begin{align*}
  c & \in r_n^2, & \{ \text{by definition} \} \\
  \bar{c} & \not\in r_n^2, & \{ u(\varphi), \text{pp}_n^1 \cap \text{ep}_n^1 \cap \text{pp}_n = \emptyset \} \\
  \bar{c} & \not\in s_n^2, & \{ \text{pp}_n^1 \cap (\text{ep}_n^2 \cup \text{pp}_n^2) = \emptyset \}
\end{align*}
\]

Hence \( c \in \text{ep}_{n+1}^2, \bar{c} \not\in \text{ep}_{n+1}^2 \) and \( c, \bar{c} \not\in \text{pp}_{n+1}^2 \).

It is easy to show that all the above equations hold. Moreover, a similar argument as before, proves the port-unicity. This also completes all the cases for \( f_1 \). A similar argument applies for \( f_2 \).

As a consequence of the above proposition, \( \vartheta, \varphi \) and \( \psi \) have disjoint domains, are port unique and contain disjoint sets of ports. Consequently, the total sums \( \vartheta \leftrightarrow \psi, \vartheta \leftrightarrow \varphi \) and \( \varphi \leftrightarrow \psi \) are port unique and

\[
\vartheta \leftrightarrow \psi = \vartheta + \psi, \quad \vartheta \leftrightarrow \varphi = \vartheta + \varphi, \quad \varphi \leftrightarrow \psi = \varphi + \psi
\]

\[\Box\]

Lemma 4 \( F_1 \otimes F_2 \) is closed.

**Proof:** To see that \( F_1 \otimes F_2 \) is closed, let \( f \in (N \xrightarrow{u} [M^*]) \overset{I, O, P}{\rightarrow} (N \xrightarrow{u} [M^*]) \), and assume that

\[\forall \theta : \exists f' \in F_1 \otimes F_2 : f(\theta) = f'(\theta).\]

The definition of \( \otimes \) implies that for any \( \theta \) there are \( f_1 \in F_1, f_2 \in F_2 \) such that:

\[
f(\theta) = \text{rng}_{I, O, P}(\theta, \varphi + \psi) \quad \text{where} \quad \varphi = f_1(\vartheta + \psi), \quad \psi = f_2(\vartheta + \varphi), \quad \vartheta = \text{dom}_{I, O, P}(\theta, \varphi + \psi)
\]

By the definition of \( \otimes \), it follows that \( f \in F_1 \otimes F_2 \).

As a consequence of the above lemmas \( F_1 \otimes F_2 \) is a mobile component.

**Theorem 13** \( F_1 \otimes F_2 \subseteq (N \xrightarrow{u} [M^*]) \overset{I, O, P}{\rightarrow} (N \xrightarrow{u} [M^*]) \) is a mobile component.

**Proof:** A consequence of Lemmas 1, 4, 2 and 3. \[\Box\]
